$$\text{Price} \times q_0 = \text{TR}$$

If the firm  
produces  $q_0$   
units

If the firm  
produces  $q_0$  it  
pays this Fixed  
Cost

If the firm “shuts down”, the firm  
produces zero units

$$q = 0$$

If the firm wants to keep the plant, it must continue to pay the **Fixed Cost** which is the same even though  $q=0$

Total Revenue is zero

$$\text{Loss} = \text{TR} - \text{TC}$$

Total Cost is just the FCC

Loss

Variable Cost is zero

In this case, the firm  
should produce  $q_0$  at  
a loss instead of  
shutting down

If the firm  
produces zero  
units it pays this  
same Fixed  
Cost

Producing at a loss is a “short run” decision: The firm would not want to close the plant and get out of the industry as soon as the price becomes too low to make a profit

The firm waits and if in the “long run” the price is still too low to make a profit, the firms then closes the plant and leaves the industry

The firm “exits” the industry in  
the long run

To minimize the  
loss, the firm must  
produce  $q_0$

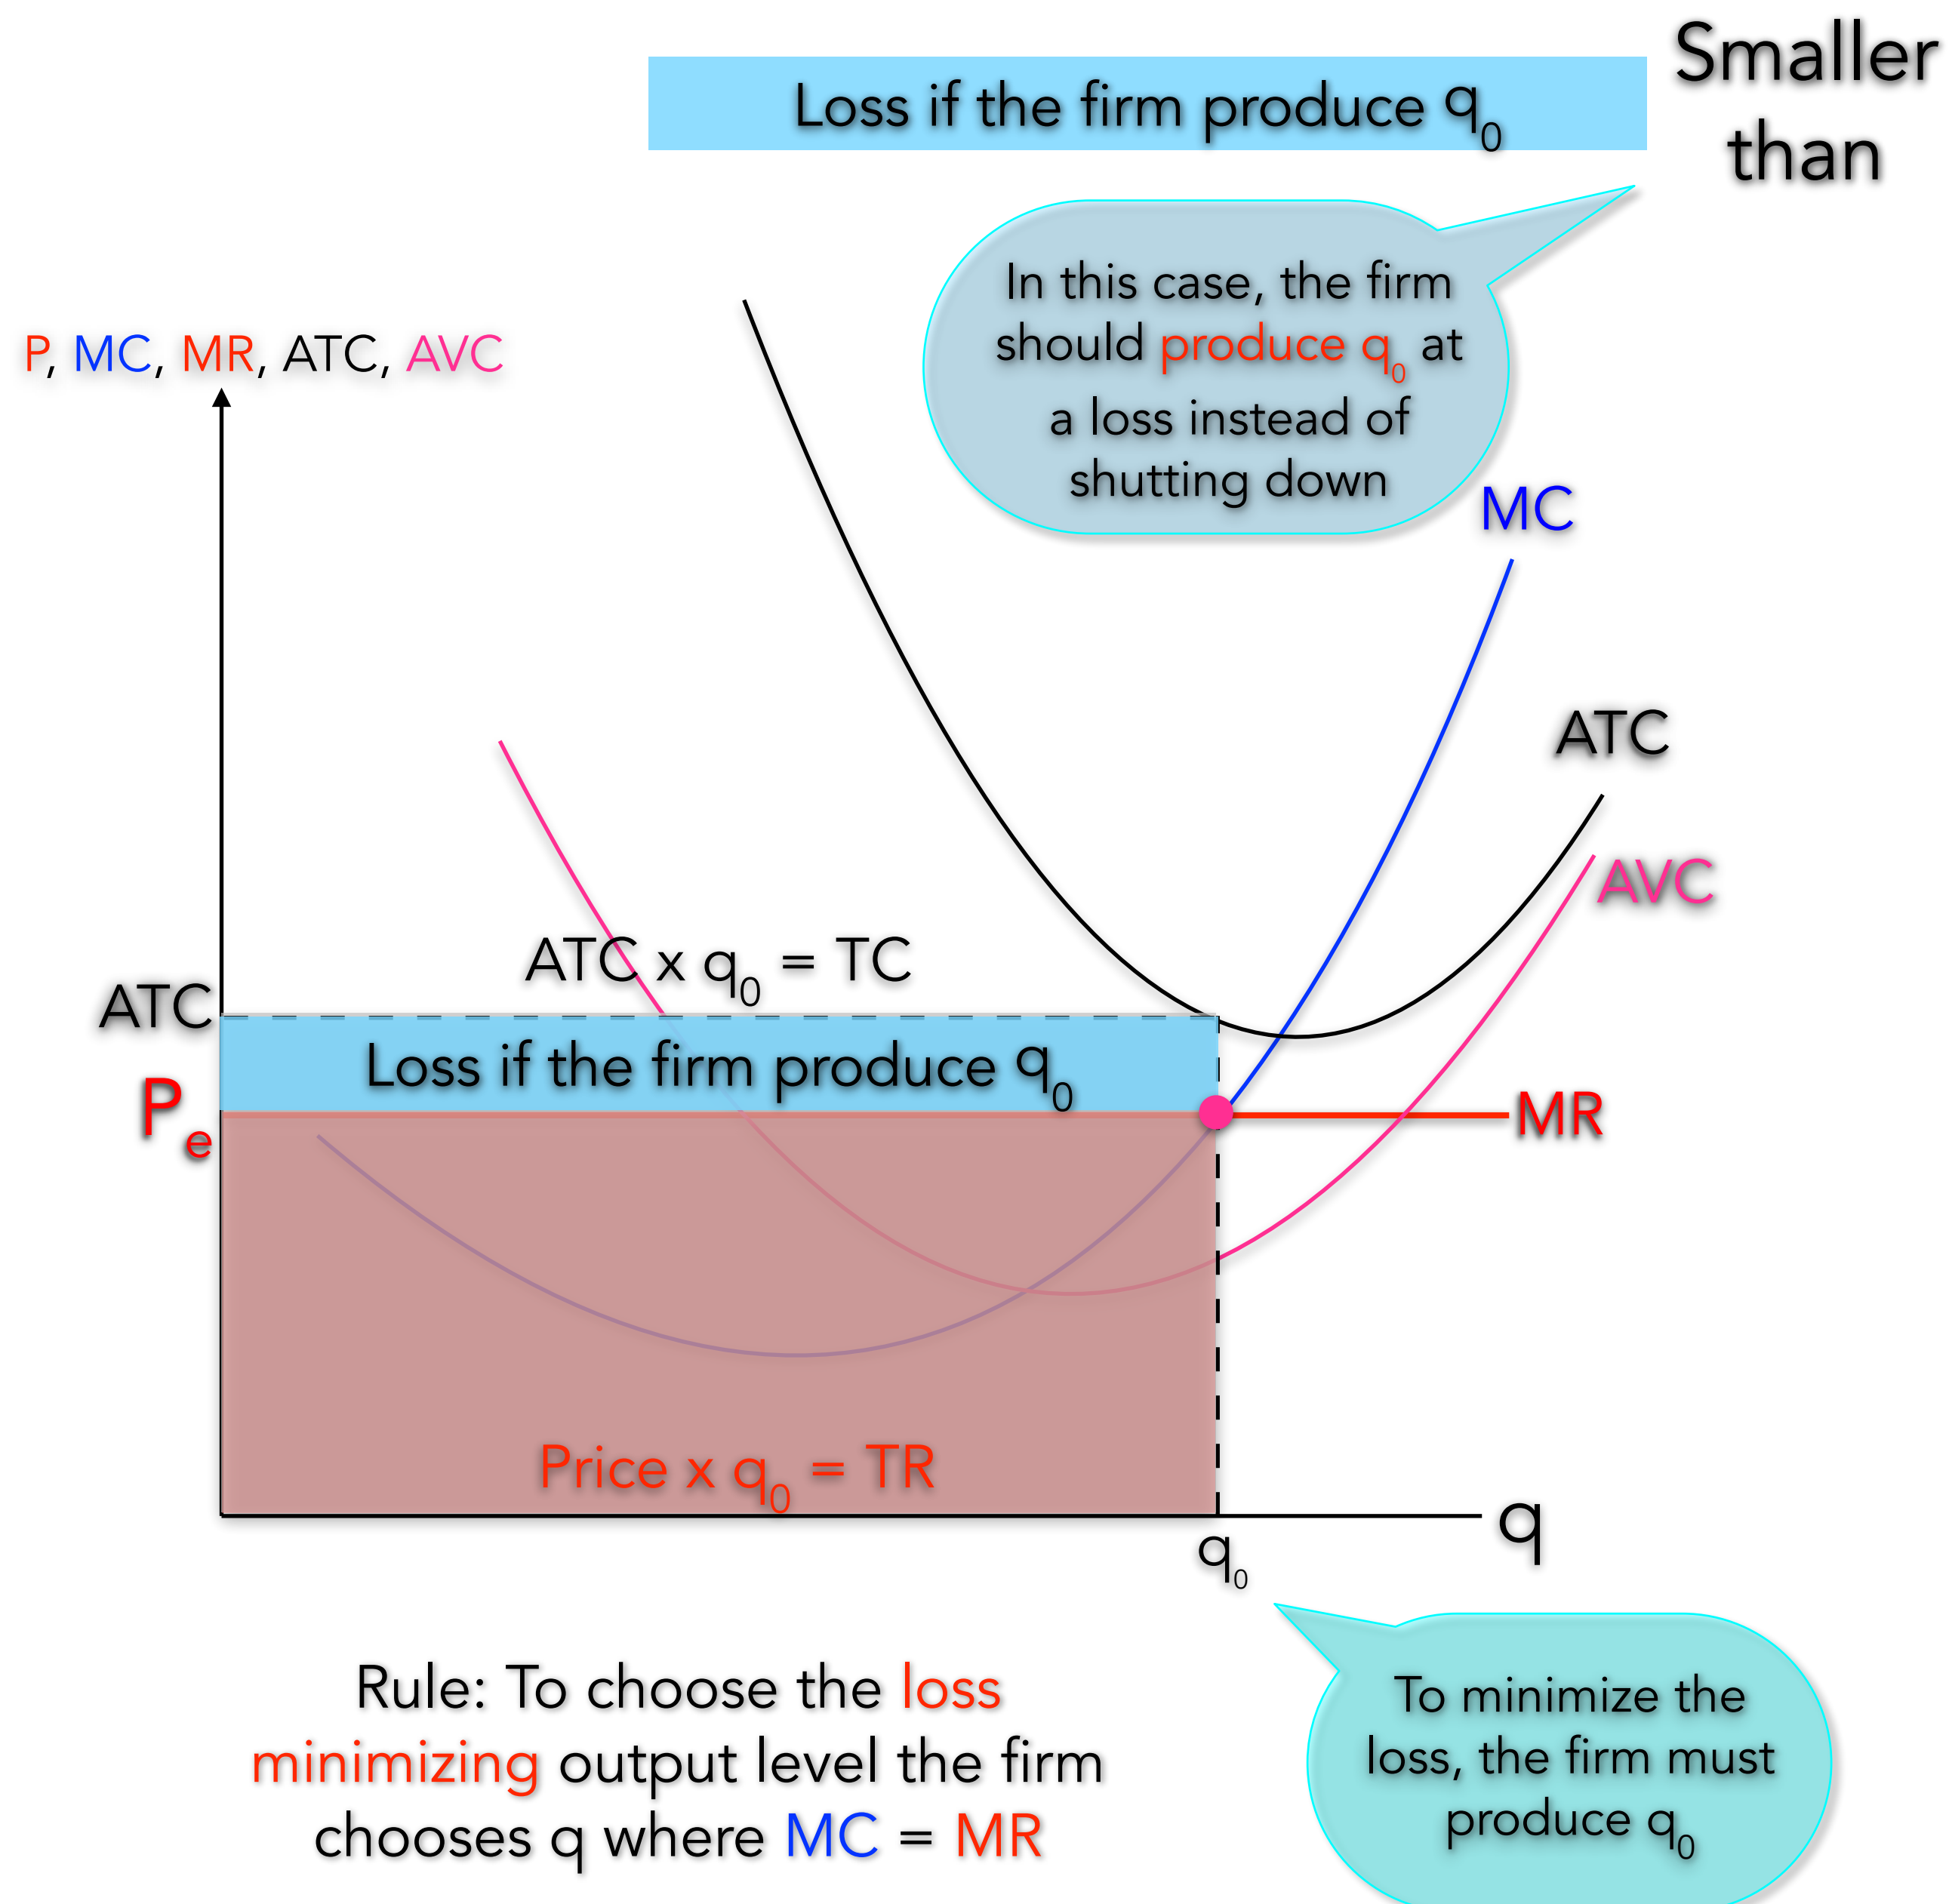

P, MC, MR, ATC, AVC

When the **price is too low**, the firm must decide whether it should **produce** at a loss or **shut down**

Rule: To choose the **loss minimizing** output level the firm chooses  $q$  where **MC** = **MR**

When the **price is too low**, the firm must decide whether it should **produce** at a loss or **shut down**

Loss if the firm shuts down = FC

**Producing at a loss** is a "**short run**" decision: The firm would not want to close the plant and get out of the industry as soon as the price becomes too low to make a profit

The firm waits and if in the "**long run**" the price is still too low to make a profit, the firms then closes the plant and leaves the industry

The firm "**exits**" the industry in the **long run**
