

Does the US economy has a self correcting mechanism?

YES

- When there is “too little spending”-Firms unable to sell all their production-

● The economy experiences a recessionary gap.

- Wages decrease, AS shifts right, prices decrease
increasing AD.

BUT

During Recessions, **wages do not easily fall...**

Firms prefer to fire unskilled workers and keep skilled workers **at the same pay** (Job security increases productivity and reduces the cost of inexperience and training)

o Recessionary gaps are longer because wages and prices do easily not fall

Selfcorrecting mechanism operates only weakly to cure recession

And thus there is an argument to be made **in favor** of stabilization policies
during recessions
